

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 one DS0 on the switch per assigned channel units at the RT. This is possible
2 because, statistically, a large portion of served customers are not actually
3 using their service at any given time. Related capabilities allow the GR-303
4 interface to accommodate integrated BRI lines.

5 Because the GR-303 interface group defines a dynamic (instead of
6 dedicated) relationship between DS0 switch ports and RT channel units, it
7 cannot be managed with the same OSS used for copper feeder and TR-008
8 loops. It was necessary to define a new set of OSS capabilities and
9 operational methods to support GR-303 IDLC. GR-303 IDLC also requires a
10 new type of digital switch port. Thus, the huge existing investment in
11 modern digital switch ports that support TR-008 IDLC would have to be
12 replaced and stranded to deploy the GR-303 interface widely.

13
14 **Q. Has Verizon VA deployed the GR-303 interfaces in its network?**

15 **A. No.** Although GR-303 provides potential cost benefits as a result of the
16 concentration feature described above, these benefits are offset by the very
17 high cost of deploying the new OSS functionality and digital switch ports
18 required to support GR-303. For these reasons, the industry has implemented
19 GR-303 only on a very limited basis, and Verizon VA has not implemented it
20 at all in its existing network.

21
22 **Q. Which of the two COT interfaces — integrated or universal — would be**

VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS

1 **used in designing an efficient, forward-looking network?**

2 A. Both would be used, depending on the application. Fiber-fed DLC switched
3 services are provisioned using IDLC in the forward-looking model. UDLC
4 or all-copper facilities must be used to provide other services such as
5 individual two-wire unbundled analog loops, private non-switched services,
6 payphone services, data services like ISDN and DDS, and others.

7

8 **Q. Why would UDLC be necessary to provide access to an unbundled loop?**

9 A. In order to access a single UNE loop, a physical point of interconnection is
10 needed. As noted above, in a TR-008 IDLC configuration, digital interface
11 ports on digital circuit switches are provided in groups of 24 DS0 channels
12 called DS1s. Once multiplexed at the RT, the individual, dedicated DS0
13 channels remain grouped in a 24-channel DS1 format all the way to the
14 digital interface ports on the switch. TR-008 equipment and software does
15 not contain the operational capability to break the electronic connection
16 between the individual channel units and the associated switch ports.
17 Because IDLC delivers signals directly to the switch in a multiplexed DS1
18 format, IDLC does not allow CLECs to connect to individual loops (such as
19 through a physical two-wire connection), and UDLC or copper cable must be
20 used instead. Thus, based on currently available technology, to unbundle a
21 loop from a TR-008 IDLC assignment, the distribution subloop must be
22 physically reconnected to a different RT channel unit associated with a

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 UDLC interface, or the entire loop must be rearranged to a copper or UDLC
2 loop. In operating practice, the whole loop rearrangement is the preferred
3 method, since it avoids wiring work in the FDI.

4 Though it is hypothetically possible to support unbundling of
5 individual loops using the GR-303 IDLC interface, the technology necessary
6 to support such unbundling is not presently available. The GR-303 interface
7 allows RTs to rearrange DS0 connection for an RT channel from one GR-303
8 DS1 group to another. In theory, one of the GR-303 groups could belong to a
9 CLEC, thus permitting the CLEC to gain access to an individual RT channel.
10 However, this feature would require developing industry standards for OSS
11 and other technical interfaces to support a multi-user environment. It also
12 would require RT suppliers to develop security, error-protection, and other
13 operational capabilities necessary to support multiple users. To date, no such
14 standards or capabilities have been developed, and Verizon VA is unaware of
15 any efforts by the suppliers of OSS, RT and COT equipment to develop or
16 make such functionality available. Thus, it is not possible, based on
17 presently-available technology, to unbundle individual loops that are served
18 with a GR-303 IDLC interface.

19

20 **Q. Are there still circumstances in which it is more cost-effective to deploy**
21 **an all-copper loop?**

VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS

1 A. Yes. Where customers are located close to the central office, an all-copper
2 solution often will be economically more efficient than fiber-fed DLC. On
3 these shorter routes, it is not necessary to use the costly network add-ons
4 (e.g., heavier gauge cables, load coils, repeaters) used on longer copper
5 loops, and using copper cables on these shorter loops also eliminates the
6 costly outside enclosures that must be installed with fiber-fed facilities.

7

8 ***b) Development of forward-looking assumptions about***
9 ***loop architecture***

10 **Q. How does Verizon's current network compare to a forward-looking**
11 **network?**

12 A. In a forward-looking network, the long-term objective is to work towards a
13 predominantly fiber-fed DLC network, reducing the copper cable length to
14 the customer. Nevertheless, as just described, copper cables are and will
15 continue to be the economically efficient design choice for many feeder loops
16 serving customers located closest to the serving wire center. Thus, the
17 forward-looking network would still have copper loops but would have an
18 increased percentage of fiber-fed DLC loops. Presently, Verizon VA's
19 network utilizes a mix of all-copper and fiber-fed loops, but because much of
20 Verizon VA's network was built before the development of optical DLC
21 technology, the large majority of Verizon VA's loops use all-copper feeder.
22 Verizon VA does place most new feeder capacity using fiber-fed DLC,

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 however, so the percentage of optical fiber feeder facilities should slowly
2 increase over time.

3
4 **Q. Describe the loop architecture utilized in the forward-looking network**
5 **assumed for the recurring studies.**

6 A. Verizon VA's forward-looking network includes a combination of 1) fiber-
7 fed DLC with copper sub-feeder and distribution cables, 2) fiber cable to a
8 building, and 3) all-copper feeder and distribution loops. To make Verizon
9 VA's study forward-looking, it was necessary to develop realistic
10 assumptions about the relative percentages of loops that would be
11 constructed using each type of facility, without regard to the mix of facilities
12 currently in service with Verizon VA's network. Verizon VA's study
13 assumed that all-copper loops would be used to serve only customers closer
14 to the central office and that fiber-fed DLC would be used for longer loops.
15 Thus, Verizon VA's combined design strategy (copper and fiber) reflects the
16 cost-effectiveness of all-copper loops on many shorter routes while
17 eliminating costly network components required for longer copper loop
18 designs (*e.g.*, heavier gauge cables, load coils, repeaters).

19 In addition, Verizon VA's loop study further recognizes that, for
20 shorter loops with a large number of customers at a single location, it is more
21 efficient to use fiber-fed DLC instead of copper feeder facilities. Consistent
22 with forward-looking economics, the cost studies therefore assume a fiber-to-

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 the-building loop architecture for all locations having a demand greater than
2 150 lines.

3

4 **Q. How did Verizon VA determine the point at which it would be**
5 **economically efficient to use optical DLC feeder facilities?**

6 A. When calculating the forward-looking cost of the loops in a wire center,
7 Verizon VA's Loop Cost Analysis Model (LCAM) (see Cost Manual,
8 Attachment B) uses a designated breakpoint to determine whether all-copper
9 feeder cable or a combination of fiber-fed DLC and copper should be
10 calculated. The copper/fiber breakpoint is a measurement in feet or kilofeet
11 (kf) of feeder cable where it would be more economical to install fiber feeder
12 cables instead of copper feeder cables. Verizon VA performed cost
13 calculations at various feeder lengths through the LCAM model to determine
14 the lowest cost of installing all-copper versus optical DLC feeder facilities.
15 Verizon VA used these calculations to determine the feeder length beyond
16 which it would be efficient to install optical DLC feeder facilities.

17

18 **Q. What was the result of Verizon VA's analysis of the copper/fiber**
19 **breakpoint?**

20 A. The results of the LCAM breakpoint calculations are summarized in
21 Attachment D to this testimony. As these results show, Verizon VA's
22 sensitivity analysis demonstrated an immaterial difference in cost between

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 the fiber and copper alternatives in the range of three kf to five kf of feeder
2 cable. Verizon VA selected the middle of this range, four kf, as the
3 economic breakpoint for Virginia feeder. When this breakpoint was applied
4 to all of the loops served by Verizon VA and the loops serving highly
5 concentrated customer locations were taken into account, Verizon VA
6 calculated that, in the most efficient forward-looking network, 17.7% of
7 Verizon VA's loops would be all copper, and the remaining 82.3% of the
8 loops would be fiber-fed DLC. Among the fiber-fed DLC loops, Verizon
9 VA further assumed that 30% would be UDLC and 70% would be IDLC,
10 with the result that 24.7% of all loops would use UDLC and 57.6% would
11 use IDLC. As an aggressive forward-looking assumption, Verizon VA then
12 assumed that 10% of all loops would be served via GR-303 interfaces.

13

14 **Q. How was the percentage of loops on IDLC versus UDLC determined for**
15 **the forward-looking network?**

16 **A. The percentage of loops using IDLC versus UDLC was determined by**
17 **developing a forward-looking assumption based on Verizon VA's experience**
18 **deploying these technologies in the current network. Because of the need to**
19 **support unbundled loops and private lines (non-switched services), Verizon**
20 **VA has found it necessary to install UDLC for approximately 30% of the**
21 **fiber-fed loops on which DLC has been installed in the last three years.**
22 **Verizon continues to install UDLC because, as explained above, UDLC is**

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 necessary to provision certain services, among them the two-wire analog
2 unbundled loop connected to a CLEC collocation arrangement. Thus, in a
3 forward-looking network in which Verizon continues to have obligations
4 under § 251 of the Telecommunications Act, Verizon VA would have to
5 maintain a share of UDLC and could not install an all-IDLC network.

6 In the remaining 70% of fiber DLC installations in the past three
7 years, Verizon VA has been able to use IDLC. Verizon VA's actual
8 deployment of this forward-looking technology when replacing or building
9 new facilities was used as a basis for estimating the make-up of the network
10 at the end of the forward-looking planning period. Verizon VA assumed that
11 the entire forward-looking network would be comprised of the efficient mix
12 reflected by the mix of technologies it expects to continue to deploy over the
13 planning period.

14
15 **Q. Is there any reason to believe that the need for UDLC will decrease in**
16 **the foreseeable future?**

17 **A. No. In fact, Verizon VA expects that the need for UDLC could actually**
18 increase as the demand for non-switched data services increases. In any
19 event, there is no indication that UDLC will not be needed to unbundle loops
20 efficiently at any time in the foreseeable future.

21

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 **Q. How was the percentage of loops using TR-008 versus GR-303**
2 **determined?**

3 A. As discussed, an assumption was made that the forward-looking percentage
4 of GR-303 over the study period would be 10% of total lines. The remaining
5 percentage of DLC would be TR-008. As explained in more detail in the
6 discussion of switching later in this testimony, most digital switches
7 deployed in Verizon VA's network are TR-008-compatible, not GR-303-
8 compatible. Verizon VA does not expect that to change in the foreseeable
9 future. Moreover, Verizon VA has not found it economically efficient to
10 deploy significant quantities of GR-303 loops. Thus, as noted, based on
11 Verizon VA's experience, the assumption that 10% of all lines would be
12 served with GR-303 is very aggressive and is forward-looking.

13
14 **Q. Is the distribution plant analyzed in Verizon VA's cost studies consistent**
15 **with a modern forward-looking network?**

16 A. Yes. As previously discussed, the FDI and SAI locations in an efficient loop
17 network are selected to economically maximize the portion of the loop length
18 that travels on feeder facilities. The SAI and FDI locations used in the cost
19 studies were derived from the actual Verizon VA network and are fully
20 consistent with these principles. The efficiency of optical loop feeder
21 systems is determined chiefly by the density of the lines in the area served.
22 This is because the RT electronics and supporting structures represent the

VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS

1 majority of the cost of optical loop feeder systems. The smallest RT unit that
2 is economically efficient to deploy with existing technology provides
3 capacity for about 224 customer lines. As noted above, when the total line
4 demand is large enough, in locations such as large multi-unit housing
5 complexes, business parks, and malls, it is economically feasible to place an
6 RT at the customer location and entirely eliminate the need for distribution
7 cable. In all other situations, copper sub-feeder and distribution cable is
8 required in the forward-looking model to aggregate enough lines at the RT to
9 make it efficient. The loop models used in Verizon VA's cost studies
10 properly reflect the mixture of optical DLC, copper feeder and sub-feeder,
11 and copper distribution cable required to address efficiently the needs of
12 different areas in Virginia with varying densities.

13
14 *c) Utilization Factors for Local Loop Components*

15 **Q. What utilization factors did Verizon VA use for its loop cost study?**

16 **A.** Verizon VA assumed the following forward-looking utilization rates for loop
17 facilities: [VERIZON VA PROPRIETARY BEGINS] XXX [VERIZON
18 VA PROPRIETARY ENDS] for copper feeder and RT common
19 electronics, [VERIZON VA PROPRIETARY BEGINS] XXX [VERIZON
20 VA PROPRIETARY ENDS] for RT service plug-ins, [VERIZON VA
21 PROPRIETARY BEGINS] XXX [VERIZON VA PROPRIETARY
22 ENDS] for fiber strand, and [VERIZON VA PROPRIETARY BEGINS]

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 **XXX [VERIZON VA PROPRIETARY ENDS]** for copper distribution
2 cable.

3

4 **Q. How were these utilization rates determined?**

5 **A. All of these utilization rates, with the exception of the utilization rate for**
6 **service plug-ins, were based on Verizon VA's current utilization rates.**

7

8 **Q. Are the utilization rates based on Verizon's current utilization rates**
9 **forward-looking?**

10 **A. Yes. As discussed above and explained below in more detail, Verizon VA's**
11 **actual utilization rates for copper feeder cable, RT common electronics, fiber**
12 **strand, and copper distribution cable reflect the use of sound engineering**
13 **principles to achieve the most efficient network design. These rates have**
14 **been stable in Verizon VA's network for years, and there is no factual or**
15 **theoretical basis to believe that these utilization rates would be different in a**
16 **forward-looking network. The most significant change in the forward-**
17 **looking model — the substitution of DLC for copper feeder facilities in a**
18 **large fraction of the plant — has no effect on utilization for reasons explained**
19 **below. This is no different from the conclusion that the forward-looking**
20 **model does not require changing the location of distribution areas within**
21 **Verizon VA's network, because the forward-looking assumptions do not**
22 **change the volume and nature of the demand that Verizon VA will serve.**

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 Thus, Verizon VA's actual utilization rates represent the best measure
2 of expected utilization rates in a forward-looking network, and any increase
3 in these utilization rates would come at the expense of increased costs and/or
4 reduced service quality.

5

6 **i) Copper Feeder and RT Common Electronics**

7 **Q. How does Verizon VA calculate the utilization rates for copper feeder**
8 **cable and RT common electronics?**

9 **A. In the context of feeder facilities, utilization is defined as the ratio of (a) the**
10 **number of loops or loop-equivalents (a copper pair and a DS0 channel on a**
11 **DLC system supply an equivalent unit of feeder capacity) that the installed**
12 **feeder capacity can support, to (b) the number of loops or loop-equivalents**
13 **actually occupied by working customer loops. In the case of the copper**
14 **feeder, the installed capacity is equal to the number of pairs connected to the**
15 **feeder side of the FDI. For DLC common electronics (which represent the**
16 **loop equivalents when using fiber feeder), the installed capacity is equal to**
17 **the total number of lines that can be supported when all of the installed**
18 **channel bank shelves in the RT (i.e., the common electronics) are filled with**
19 **service plug-in cards. For example, each channel bank shelf on the LiteSpan**
20 **2000 RT system can support 224 lines. Thus, the total common electronics**
21 **capacity of a LiteSpan 2000 RT equals the number of installed channel bank**
22 **shelves multiplied by 224.**

VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS

1

2 **Q. Why do copper feeder and RT common electronics have the same**
3 **utilization rates?**

4 **A. DLC technology was specifically designed as a substitute for copper feeder**
5 **cable. Not surprisingly, a DLC system designed to address the same capacity**
6 **planning issues that exist for copper feeder facilities has similar**
7 **characteristics to the copper feeder facilities. Thus, copper feeder and RT**
8 **common electronics share similar characteristics critical to planning — size**
9 **of demand served by each facility, capacity unit breakage, and engineering**
10 **lead time — that contribute to their having the same utilization rates.**

11 The first characteristic shared by copper feeder cable and RT
12 common electronics is the nature of the demand served by each. A feeder
13 route, whether it uses copper or fiber cable, typically serves a large number
14 of subscribers — at times 10,000 or more — and may cover as much as a
15 quarter of the lines in a wire center. For capacity planning, the feeder route is
16 divided into smaller units, called UAAs for copper feeder and CSAs for DLC
17 feeder. UAAs and CSAs are similar in size, usually covering two or three
18 distribution areas and approximately 1,000 access lines. Within each feeder
19 route, installed capacity units are dedicated to a particular distribution area.
20 Thus, an installed copper feeder pair may be placed in a large feeder route
21 structure and planned on the basis of UAAs, but it nevertheless is terminated
22 at a particular FDI cross-box and thus is dedicated to a particular distribution

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 area. Likewise, each DLC equivalent of a copper pair is ultimately dedicated
2 to a particular distribution area.

3 The second characteristic shared by copper feeder cable and RT
4 common electronics is the engineering lead time required to install additional
5 units of capacity. Feeder facilities are designed with the expectation that they
6 will be augmented over time to accommodate demand growth. Each year an
7 engineer reviews current feeder utilization and forecasted growth on every
8 feeder segment to determine whether demand growth will require a capacity
9 addition on that segment in the coming year. Though the logistics of
10 installing copper feeder cable and RT common electronics are quite different,
11 the planning and installation processes for each require a similar amount of
12 time. Thus, copper feeder cable and RT common electronics are evaluated at
13 similar intervals to determine when additional capacity will be required.

14 The third characteristic shared by copper feeder cable and RT
15 common electronics is the effect of breakage on the capacity planning
16 process. The task of the feeder engineer during the planning process is to
17 ensure that the capacity of installed feeder facilities will be sufficient to meet
18 the forecasted demand at each distribution area. The standard feeder
19 engineering process used in the industry is referred to as "fill-at-relief"
20 planning. A minimum margin of spare capacity is needed to allow efficient
21 feeder operation, administration and management. Industry operating
22 experience has established this margin as 15% of installed capacity for

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 copper feeder and 10% for DLC feeder electronics. Thus, the maximum
2 experienced utilization at any FDI at any point in time should be 85% for
3 copper feeder and 90% for DLC feeder electronics. The feeder planning
4 process is designed to provide additional capacity before this minimum
5 margin is depleted.

6 "Breakage" has a similar impact on the planning process for both
7 copper feeder facilities and RT common electronics, further contributing to
8 their similar utilization levels. In the case of copper feeder cable, capacity is
9 most efficiently installed in increments of 100 pairs. Similarly, RT common
10 electronics must be augmented in increments corresponding to physical shelf
11 units that accommodate 224 service channel units. However, as noted, both
12 these facilities must be dedicated to relatively small distribution areas, most
13 of which require a few hundred feeder pairs (whether copper or DLC-derived
14 pairs) in service. Because copper feeder tends to serve distribution areas with
15 approximately half as many access lines as an RT terminal, breakage has a
16 nearly identical effect on utilization levels for both copper feeder and RT
17 common electronics. In both cases, utilization in a particular distribution
18 area drops significantly whenever it is necessary to install additional feeder
19 capacity for that distribution area.

20

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

ii) RT Service Plug-In Utilization

1
2 **Q. What is the relationship between RT service plug-ins (or channel units)**
3 **and common equipment?**

4 A. Each remote terminal contains two types of electronic equipment: common
5 equipment and service plug-ins. As discussed in the previous section, the
6 common equipment consists primarily of shelf units that have a fixed number
7 of ports (typically 224) for service plug-ins. A "service plug-in" provides
8 transmission and signaling functions (*e.g.*, analog to digital conversion and
9 line power) for a small number of individual lines (eight or fewer). The
10 service channel units represent a significant portion of the DLC cost for each
11 loop. For this reason, they have been designed so that they can be added in
12 small numbers as line demand increases, provided that the installed RT
13 common equipment shelf capacity is sufficient to accommodate additional
14 plug-in cards.

15
16 **Q. How do the characteristics of service plug-ins affect utilization?**

17 A. Because the service plug-ins — also called channel service units — are
18 relatively easy to install, can be ordered on short intervals, and are available
19 in very small capacity increments, RT service channel capacity is reviewed
20 continuously and additions can be ordered as needed. Normally, additions
21 are sized to last six to 12 months to avoid the added costs associated with
22 having to constantly dispatch technicians to each RT site. For these reasons,

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 it should be possible to maintain the utilization rates for RT service plug-ins
2 at a significantly higher level than the utilization rates for common
3 equipment.

4
5 **Q. How did Verizon VA calculate the utilization factor for service plug-ins?**

6 **A. In this particular case, Verizon VA determined that its current utilization**
7 **rates were not the best measure of forward-looking utilization rates. Thus,**
8 **Verizon VA determined the proper forward-looking utilization rates by**
9 **making appropriate forward-looking adjustments to the maximum theoretical**
10 **utilization rate for service plug-ins.**

11 Specifically, the maximum theoretical utilization rate for plug-ins at a
12 remote terminal is 90% (this is the same maximum theoretical for common
13 equipment). Average achieved utilization in a forward-looking network
14 would fall below this rate because of the need for sufficient capacity to
15 accommodate short-term growth and demand peaks. Forward-looking
16 utilization also would be affected by the beneficial practice of leaving service
17 plug-ins connected at recently-vacated customer premises. This practice
18 reduces the amount of technician effort (and thus the costs incurred) to
19 reactivate service at that customer premises when a new occupant orders
20 service. Because the duration of a vacancy can be as short as a few days, it
21 may in some cases be more cost-effective to leave service plug-ins connected

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 to a particular distribution pair for a period of time following the
2 disconnection of service.

3 Based on the experience of Verizon VA's engineers and the
4 characteristics of service plug-ins, Verizon VA determined that an
5 **[VERIZON VA PROPRIETARY BEGINS] XXX [VERIZON VA**
6 **PROPRIETARY ENDS]** utilization factor for service plug-ins represents an
7 appropriate estimate of the utilization of service plug-ins in a forward-
8 looking network.

9

10 **iii) Fiber Strand Utilization**

11 **Q. What is fiber strand?**

12 A. "Fiber strand" refers to all of the fiber optic cable installed in Verizon VA's
13 local exchange network, whether used for feeder facilities or interoffice
14 facilities.

15

16 **Q. Please describe the characteristics of fiber strand that affect utilization.**

17 A. The fiber cables used in local exchange networks consist of an outer
18 protective tube containing up to several hundred, hair-thin fiber strands.
19 These strands carry the optical signals used by both interoffice and feeder
20 transport systems, and it is not unusual for a fiber cable to supply strands to
21 both feeder and interoffice facilities.

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 In most fiber cables used in the local network, the fiber strands within
2 the outer protective tube are manufactured in groups of 12 called "ribbons."
3 The group of 12 strands is sealed together in a thin, ribbon-like, plastic
4 casing. This design is economically efficient to manufacture in large
5 quantities, and it also makes handling and deployment in the outside
6 environment easier than working with hundreds of individual, identical loose
7 fibers.

8 The 12-fiber ribbon structure has a particularly significant impact on
9 the construction and utilization of fiber cable. Existing construction tools
10 and methods make it far easier and more cost-effective to work with fiber
11 cable in whole-ribbon increments. For this reason, fiber is allocated and
12 dedicated by ribbon in most applications. Thus, in the case of fiber cables
13 used for DLC facilities, it is less expensive to allocate to each RT site an
14 entire ribbon of fiber, even though each RT typically requires only four
15 functioning strands. Though this leaves the remaining eight strands unused,
16 thus reduces the utilization rate, the cost associated with trying to divide each
17 ribbon into individual strands and resplice them individually to use at other
18 sites far outweighs the very low incremental cost of the additional fiber
19 strands.

20
21 **Q. Please provide an example of how the ribbon structure impacts fiber**
22 **strand utilization on a feeder route.**

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 A. Consider as an example a fiber feeder route serving eight remote terminals at
2 various distances from the central office. Because of the cost savings
3 associated with dedicating a full ribbon to each RT, the feeder route would
4 require a cable emerging from the central office with no fewer than eight
5 ribbons. (On this route, an additional ribbon would be required as
6 administrative spare, making the actual minimum requirement nine ribbons.)
7 Because it is not possible to purchase a cable containing only nine ribbons,
8 the least expensive cable that Verizon VA could purchase for this feeder
9 route would be a 12-ribbon cable (containing 144 individual strands). After
10 connecting one ribbon to each of the eight RTs and then four strands of each
11 ribbon to each RT, a total of 32 strands out of a possible 144 would be in use.
12 This produces a fiber strand utilization factor of 22.22%. (If utilization were
13 measured at the ribbon level, utilization would be eight of 12 total ribbons, or
14 67.67%.) Even if the particular feeder route permitted using all three of the
15 unused ribbons (assuming one ribbon for administrative spare) for interoffice
16 transport, the resulting strand utilization for that route would be 68 of a total
17 144 strands, or 47.2%.

18 Though this example might appear, superficially, to demonstrate
19 inefficiency due to a large amount of wasted fiber strand, the alternative
20 would in fact entail much higher costs. To reduce this spare capacity, it
21 would be necessary to install fiber capacity using either combinations of
22 smaller cable sizes or cable containing individual fiber strands instead of

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 ribbons. Even where such alternative cable sizes or configurations are
2 available, they are not always less expensive than purchasing larger cables
3 containing fibers grouped into ribbons. Moreover, either alternative produces
4 significantly higher installation and maintenance costs, particularly if
5 installation or maintenance requires working with individual fiber strands
6 instead of ribbons. Thus, the mere possibility of a small savings in fiber
7 cable costs would be far outweighed by the high costs associated with
8 installing and maintaining such fiber configurations.

9
10 **Q. Is there any basis for believing that fiber strand utilization would**
11 **increase in a forward-looking network?**

12 **A. No. The current utilization of fiber strands in Virginia is [VERIZON VA**
13 **PROPRIETARY BEGINS] XXX [VERIZON VA PROPRIETARY**
14 **ENDS]. This rate has been stable for many years, even as Verizon VA has**
15 **deployed and utilized more fiber. There is no basis to believe this utilization**
16 **rate would increase in the forward-looking network.**

17

18 **iv) Distribution Cable**

19 **Q. What utilization factor was used for copper distribution cable in Verizon**
20 **VA's studies?**

21 **A. A factor of [VERIZON VA PROPRIETARY BEGINS] XXX [VERIZON**
22 **VA PROPRIETARY ENDS] was used.**

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1

2 **Q. How was this factor derived?**

3 A. This factor is derived from the actual utilization of terminated distribution
4 pairs experienced in the Verizon VA network, with an adjustment for
5 breakage. The copper distribution utilization factor is derived from data
6 extracted from the Loop Engineering Assignment Data (LEAD) database.
7 The LEAD data identifies working, assigned and available pairs in Verizon
8 VA's outside plant. The assigned pairs are classified as F1 or F2. F1 pairs
9 are those which are fed directly from the central office. F2 pairs are those
10 which are on the distribution side of an interface (cross-box).

11

12 **Q. Why was it necessary to make a separate adjustment to the LEAD data**
13 **to account for breakage?**

14 A. The utilization of available distribution pairs, as calculated by the LEAD
15 extract, accounts for only those distribution pairs that are connected to the
16 SAI. However, due to breakage (*i.e.*, the fact that distribution cable is
17 manufactured only in certain sizes), it typically is necessary to install cables
18 containing more distribution pairs than actually need to be connected to the
19 distribution terminal. The breakage factor accounts for the fact that a
20 distribution pair requirement may be smaller than the next available cable
21 size. For example, on a distribution backbone route that requires 1,050 lines
22 emanating from the SAI in order to accommodate demand peaks, demand

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 growth, administrative spare, and other factors, the smallest sufficient cable
2 size would be a 1,200-pair distribution cable, leaving a significant number of
3 spare pairs.

4 The tapering process also contributes some measure of additional
5 breakage that cannot be calculated through the LEAD database. The tapering
6 process allows the use of smaller capacity cables further down a distribution
7 route after a sufficient number of pairs have been branched off from a
8 distribution backbone cable. In the example above, a distribution backbone
9 route that requires a 1,200-pair distribution cable to serve 1,050 lines from
10 the SAI might have two 100-pair branches at each of the first two streets
11 passed by the backbone cable. After passing those branches, only 800 pairs
12 remain to be distributed to the remaining branches. Rather than continue to
13 use a 1,200-pair cable, Verizon VA might use a smaller 900-pair cable to
14 serve the remaining branches, assuming that the cost savings associated with
15 the smaller cable size offset the costs of splicing and connecting the 900-pair
16 cable to the remaining 800 pairs. (The alternative would be to run the 1,200-
17 pair cable to the end of the distribution backbone route and branch off pairs
18 as needed.) This tapering process would produce an additional breakage of
19 100 pairs that cannot be measured from the LEAD database.

20

21 **Q. How is the distribution cable utilization factor adjusted to account for**
22 **breakage?**

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 A. Verizon VA performed an analysis to arrive at a breakage adjustment factor
2 that accounts for the necessary cable size to meet the line requirement.
3 Based on this analysis, Verizon VA made the conservative determination
4 that, on average, breakage in distribution cables required a **[VERIZON VA**
5 **PROPRIETARY BEGINS]** XXX **[VERIZON VA PROPRIETARY**
6 **ENDS]** downward adjustment to the distribution cable utilization factor. In
7 the example above, the actual unmeasured breakage would have been 12.5%
8 for the 1,200-pair cable and 16.7% for the 900-pair cable. Thus, the
9 **[VERIZON VA PROPRIETARY BEGINS]** XXX **[VERIZON VA**
10 **PROPRIETARY ENDS]** adjustment reflects a conservative estimate of the
11 breakage effects that could not be measured using the LEAD data. The
12 breakage adjustment as well as the utilization factor calculations are shown in
13 VZ-VA CS, Vol. I, Part B, Section 5.1.

14
15 **Q. What other factors account for the utilization rates for distribution**
16 **cable?**

17 A. A primary driver of distribution utilization rates is the need to accommodate
18 subscribers' needs for multiple lines.

19 Verizon VA's current experience shows that, across the network,
20 residential subscribers utilize on average 1.18 lines per subscriber location.
21 However, this demand is not spread uniformly over every customer. No
22 customer demands 1.18 lines. Individuals demand one, two, three or even

**VERIZON VIRGINIA INC.
PANEL TESTIMONY ON UNBUNDLED
NETWORK ELEMENT AND INTERCONNECTION COSTS**

1 more lines in special cases. Furthermore, concentrations of customers
2 requiring more than one line occur randomly and change over time. To
3 account for these local peaks, industry experience has proven that it is much
4 more economically efficient to build a network with at least two pairs of
5 distribution cables per subscriber to avoid the prohibitive cost and delay
6 associated with installing a new cable each time a group of subscribers on a
7 particular street orders an above-average number of additional lines. Thus,
8 the utilization rate for distribution cable can be explained in large part by the
9 difference between the efficient, forward-looking construction of two (or
10 more) distribution pairs per subscriber and the actual average utilization of
11 1.18 pairs per subscriber. Other factors such as breakage (discussed above),
12 the need to accommodate future growth, and subscriber churn (which leaves
13 some distribution pairs unused) also contribute to the utilization rate for
14 distribution cable.

15

16 **Q. Is the distribution utilization factor forward-looking?**

17 **A.** Yes. The utilization of distribution pairs has been stable in Virginia, and
18 there is no basis to anticipate that it will change significantly in the future
19 based on present or future technological improvements, efficiency gains, or
20 other forward-looking factors. Thus, using Verizon VA's current and past
21 experience to determine the distribution cable utilization factor creates an
